Suite 104

Research Triangle Park, NC 27709

2. Lineage: primary hepatocytes from deceased individuals. Liver tissue is perfused at Zen-bio with proprietary methodology and isolation medium designed to exclude non-parenchymal cells. Purity is determined to be >85% by morphology.
3. Cells for open chromatin experiments were provided fresh in suspension, but can also be ordered as frozen cryovials (HP-3001). Viability was determined by trypan blue staining and were found to be >80% viable.
